PYRROLE DERIVATIVES AS PHARMACEUTICAL AGENTS

CROSS REFERENCE TO RELATED APPLICATIONS

This application claims priority to U.S. Provisional Patent Application Serial No. 60/592,469 and Serial No. 60/592,439 filed on July 30, 2004, the
5 disclosures of which are incorporated herein by reference.

FIELD OF THE INVENTION

Compounds, compositions and methods are provided for modulating the activity of receptors and for the treatment, prevention, or amelioration of one or more
10 symptoms of disease or disorder related to the activity of the receptors.

BACKGROUND OF THE INVENTION

The nuclear receptor (NR) superfamily comprises more than 150 different
15 proteins, most of which are believed to function as ligand activated transcription factors, exerting widely different biological responses by regulating gene expression (for review, see Di Croce et al, EMBO J 18:6201-6210 (1999); Mangelsdorf, et al Cell 83:825-839 (1995); Perlmann, et al, Cell 90:391-397 (1997)). Members of this family include receptors for endogenous small, lipophilic molecules, such as steroid
20 hormones, retinoids, vitamin D and thyroid hormone.

The classical steroid receptors include the mineralocorticoid receptor (MR) (or aldosterone receptor), the estrogen receptors, ER alpha and ER beta, the androgen receptor (AR), the progesterone receptor (PR) and the glucocorticoid receptor (GR). Also closely related in structure are the estrogen related receptors (ERRs) ERR1,
25 ERR2 and ERR3. The steroid receptors perform important functions in the body related to the transcriptional homeostasis of electrolyte and water balance, growth, development and wound healing, fertility, stress responses, immunological function, and cognitive functioning (see, Assay Drug Dev. Technol., 1 (6): 843-52 (2003)). Accordingly, compounds that modulate (i.e. antagonize, agonize, partially antagonize,
30 partially agonize) the activity of steroid nuclear receptors are important pharmaceutical agents that have specific utility in a number of methods, as well as for the treatment and prevention of a wide range of diseases and disorders modulated by the activity of steroid nuclear receptors.

Members of the steroid nuclear receptor sub-family exhibit significant homology to each other and possess closely related DNA and ligand binding domains. Given the close similarity in ligand binding domains of the steroid nuclear receptors, it is not surprising that many naturally occurring and synthetic molecules possess the ability to modulate the activity of more than one steroid nuclear receptor. For example the naturally occurring glucocorticoids cortisol and corticosterone are able to modulate both the glucocorticoid receptor and the mineralocorticoid receptor under physiological conditions.

Accordingly, one approach to developing compounds that are steroid nuclear receptor modulators is to identify a core chemical scaffold that exhibits a common structural motif that provides for the ability to bind to a steroid nuclear receptor, and which in certain embodiments possesses the ability to selectively modulate one or more of the other steroid nuclear receptors. Such compounds are useful for the local or systemic treatment or prophylaxis of human and veterinary diseases, disorders and conditions that are modulated, or otherwise affected by one or more steroid nuclear receptors, or in which steroid nuclear receptor activity, is implicated.

A well-characterized example of the classical steroid receptor sub-family that is amenable to this approach is the mineralocorticoid receptor (aldosterone receptor). The mineralocorticoid receptor plays an important role in regulating electrolyte balance and blood pressure in the body (Adv. Physiol. Educ. 26(1): 8-20 (2002), and its activity is modulated in vivo through the secretion of aldosterone.

Traditionally, it was thought that aldosterone was secreted by the zona glomerulosa of the adrenal gland in response to angiotensin II, potassium and adrenocorticotrophic hormone (ACTH), and acted primarily on the epithelial cells of the kidney and colon to regulate sodium and potassium transport. More recently, it has been appreciated that aldosterone is also synthesized by endothelial cells and in vascular smooth muscle cells (VSMCs), the brain, blood vessels and myocardium where it may play a paracrine or autocrine role (Ann. N.Y. Acad. Sci. 970 89-100 (2002)).

Tissue specificity for aldosterone is conferred by the local expression of the mineralocorticoid receptor and by the activity of 11-beta hydroxysteroid dehydrogenase type 2 (11 β -HSD2), which acts to convert the cross-reactive glucocorticoids cortisol and corticosterone into cortisone and 11-dehydrocorticosterone which have significantly reduced affinity for the MR (Science, 242: 583-585 (1988)).

In humans, elevated plasma aldosterone concentrations are usually associated with hypertension, typically mediated through the effect of the hormone on sodium retention and blood volume. Hypertension affects about 5 million Americans, approximately a third of which are unaware of their condition and are not receiving treatment. Hypertension is associated with the development of cardiovascular, cardiac and renal diseases, including chronic and congestive heart failure (J. Postgrad. Med. J., 79 :634-642 (2003)), progressive renal failure (J. Am. Soc. Nephrol. ,14 :2395-2401 (2003)) and chronic and end stage renal failure (Am. J. Kid. Dis., 37 (4): 677-688 (2001)). In these conditions, elevated blood pressure appears to enhance and amplify the progressive decline in organ function in these diseases.

Aldosterone also has direct effects on brain, heart, vascular and renal tissues. In the heart, vascular and renal tissues, aldosterone action can also play a significant role in the development and progression of inflammation, scarring and fibrosis (the generation of fibrotic tissue) independently of the effects on blood pressure (Clin. Cardiol., 23 :724-730 (2000); Adv. Physiol. Educ., 26(1): 8-20 (2002); Hypertension, 26:101-111 (1995)).

In the brain, aldosterone has been linked to various cognitive dysfunctions, and aldosterone antagonists have been shown to be useful for improving cognitive function (US Application UA2002/0111337), and treating cognitive & mood dysfunctions.

In chronic heart failure (CHF), impaired cardiac function triggers a train of compensatory mechanisms, including aldosterone secretion, that ultimately leads to a worsening of symptoms and reduced survival (J. Clin. Endo & Meta, 88: (6) 2376-2383 (2003)). These changes are primarily mediated by the renin-angiotensin-aldosterone system (RAAS) and sympathetic nervous system. Activation of the RAAS leads to increases in renin, angiotensin II and aldosterone. Angiotensin II acts as a vasoconstrictor, promotes aldosterone production, and stimulates norepinephrine release from sympathetic nerve terminals to increase the heart rate. Aldosterone acts to increase blood volume, and hence blood pressure, through its action in the kidney to retain sodium.

While the net effect of these factors is to restore blood pressure, the increased peripheral vascular resistance also increases the load against which the heart works. Ultimately the increased cardiac pressure results in cardiac re-modeling, leading to lung stiffness, pulmonary edema, and breathlessness. Additionally peripheral vasoconstriction results in reduced blood flow to the skeletal muscles contributing to fatigue during exercise.

Current drug treatments for CHF are focused on relieving the symptoms of the disease, improving the quality of life, slowing disease progression, preventing hospital admission, prolonging active life, and reducing mortality. Such therapeutic approaches include the use of diuretics, angiotensin converting enzyme inhibitors (ACE inhibitors),
5 beta adrenergic receptor blockers (beta blockers), AT antagonists and calcium channel blockers to suppress the harmful effects of the neuroendocrine compensatory mechanisms such as the RAAS and beta adrenergic (sympathetic) nervous system. (Postgrad. Med. J. 79 634-642 (2003)).

Diuretics act to reduce water retention, reduce blood pressure and can act as
10 vasodilators to reduce circulatory resistance. ACE inhibitors and beta blockers have been shown to reduce mortality and improve symptom status in CHF in part by reducing angiotensin II and aldosterone levels. However angiotensin II and aldosterone typically return to normal levels with chronic therapy. Accordingly, angiotensin II receptor antagonists, which selectively block the AT1 angiotensin receptor, and
15 aldosterone antagonists, which selectively block the mineralocorticoid receptor, provide significant therapeutic benefit for the treatment of CHF (Circulation, 100 :1056-1064 (1999); N. Eng. J. Med., 341 (10) :709-718 (1999)).

In addition to aldosterone and angiotensin II, calcium channels play an important role in heart failure. In both vascular and cardiac tissue, muscle cell
20 contraction occurs when cells are depolarized from the influx of calcium through calcium channels in the cell. Calcium channel blockers inhibit muscle contraction and promote relaxation. In vascular smooth muscle this results in vessel dilation, reduced blood pressure (anti-hypertensive effect) and a reduction in the force required to pump blood by the heart. Calcium channel blockers also act on the heart to improve filling by
25 promoting relaxation of cardiac muscle in diastole. However, calcium channel blockers also reduce the force of contraction during systole (negative inotropy) and therefore are often not the drug of choice for treating heart failure.

Hypertension is not only a primary cause of the development of cardiovascular, cardiac and renal diseases, but a risk factor for the progression of these diseases
30 initiated by other mechanisms such as atherosclerosis, cardiovascular disease, ischemic heart disease, diabetes, diabetic nephropathy, chronic glomerulonephritis and polycystic kidney disease (J. Am. Soc. Nephrol., 14 :2395-2401 (2003)).

In renal failure, as with the case of chronic heart failure, a number of clinical trials have established that interruption of the RAAS cascade with ACE inhibitors is
35 beneficial in limiting renal disease (Am. J. Kid. Dis., 37 (4): 677-688 (2001). Additional

studies have also established that aldosterone antagonists can attenuate proteinuria and renal damage typically observed in progressive renal disease and offer further therapeutic benefit compared to ACE inhibitors alone (Hypertension., 31 :451-458 (1998)).

5 Many aldosterone antagonists are known. For example spironolactone, the first approved aldosterone antagonist, has been used for blocking aldosterone-dependent sodium transport in the distal tubule of the kidney in order to reduce edema and to treat essential hypertension and primary hyperaldosteronism (F. Mantero et al, Clin. Sci. Mol. Med., 45 (Suppl 1), 219s-224s (1973)). Spironolactone is also used commonly in
10 the treatment of other hyperaldosterone-related diseases such as liver cirrhosis, renal failure and congestive heart failure (F. J. Saunders et al, Aldactone; Spironolactone: A Comprehensive Review, Searle, N.Y. (1978)).

However, spironolactone is not very selective for the MR over other steroid receptors, including the androgen and progesterone receptors. This cross reactivity
15 leads to undesired side effects such as menstrual irregularity in women, and gynecomastia in men (Circulation, 107 :2512-2518 (2003)).

Eplerenone is a derivative of spironolactone that is more selective for the MR than spironolactone (Nature Reviews, 2: 177-178 (2003)). However, eplerenone has relatively low potency for the MR, induces hyperkalemia, and is primarily eliminated via
20 the kidney, making it unsuitable for patients with progressive renal failure.

Accordingly, there is a need for new modulators that are useful in the prevention, treatment, or amelioration of one or more of the symptoms of diseases or disorders associated with mineralocorticoid receptor activity. Such diseases or disorders include, but are not limited to fluid retention, edema, primary
25 hyperaldosteronism, Conn's syndrome, hypertension, high blood pressure, liver cirrhosis, cardiovascular disease, heart failure, chronic heart failure, cardiac disease, renal disease, chronic kidney disease, fibrosis, and cognitive dysfunctions.

The configuration for naturally occurring amino acid residues is generally L. When not specified the residue is the L form. As

10 used herein, the term "amino acid" refers to α -amino acids which are racemic, or of either the D- or L-configuration. The designation "d" preceding an amino acid designation (e.g., dAla, dSer, dVal, etc.) refers to the D-isomer of the amino acid. The designation "dl" preceding an amino acid designation (e.g., dlPip) refers to a mixture of the L- and D-isomers of the amino acid. It is to be understood that the chiral centers of

15 the compounds provided herein may undergo epimerization *in vivo*. As such, one of skill in the art will recognize that administration of a compound in its (*R*) form is equivalent, for compounds that undergo epimerization *in vivo*, to administration of the compound in its (*S*) form.

20 Such chiral centers may be of either the (*R*) or (*S*) configuration, or may be a mixture thereof.

Optically active (+) and (-), (*R*)- and (*S*)-, or (*D*)- and (*L*)-isomers may be prepared using chiral synthons or chiral reagents, or resolved using conventional techniques, such as reverse phase HPLC.

B. FORMULATION OF PHARMACEUTICAL COMPOSITIONS

The pharmaceutical compositions provided herein contain therapeutically effective amounts of one or more of the compounds or compositions, or pharmaceutically acceptable derivatives thereof, provided herein that are useful in the prevention, treatment, or amelioration of human and veterinary diseases, disorders and conditions mediated by, or otherwise affected by one or more steroid nuclear receptors, or in which steroid nuclear receptor activity, is implicated, as defined herein. The compounds, compositions, or pharmaceutically acceptable derivatives thereof are preferably formulated into suitable pharmaceutical preparations such as solutions, suspensions, tablets, dispersible tablets, pills, capsules, powders, sustained release formulations or elixirs, for oral administration or in sterile solutions or suspensions for parenteral administration, as well as transdermal patch preparation and dry powder inhalers. Typically the compounds described above are formulated into pharmaceutical compositions using techniques and procedures well known in the art (see, e.g., Ansel *Introduction to Pharmaceutical Dosage Forms, Fourth Edition* 1985, 126; Remington's *Pharmaceutical Sciences*, Mack Publishing Company, Easton, Pa., 15th Edition, 1975).

In the pharmaceutical compositions, effective concentrations of one or more compounds or pharmaceutically acceptable derivatives thereof is (are) mixed with at least one suitable pharmaceutical carrier, vehicle, diluent, or solvent. Dosage forms or compositions containing active ingredient in the range of 0.005% to 100% with the
5 balance made up from non-toxic carrier may be prepared. The contemplated compositions may contain 0.001%-100% active ingredient, preferably 0.1-85%, typically 75-95%. In addition, the compounds may be formulated as the sole pharmaceutically active ingredient in the composition or may be combined with other active ingredients.

10 The active compound is included in the pharmaceutically acceptable carrier in an amount sufficient to exert a therapeutically useful effect in the absence of undesirable side effects on the patient treated. The therapeutically effective concentration may be determined empirically by testing the compounds using *in vitro* and *in vivo* systems described herein and in International Patent Application
15 Publication Nos. 99/27365 and 00/25134 and then extrapolated therefrom for dosages for humans.

The concentration of active compound in the pharmaceutical composition will depend on absorption, inactivation and excretion rates of the active compound, the physicochemical characteristics of the compound, the dosage schedule, and amount
20 administered as well as other factors known to those of skill in the art. For example, the amount that is delivered is sufficient to ameliorate one or more of the symptoms of diseases or disorders associated with nuclear receptor activity or in which nuclear receptor activity is implicated, as described herein.

Typically, a therapeutically effective dosage should produce a serum
25 concentration of active ingredient of from about 0.1 ng/ml to about 50-100 µg/ml. The pharmaceutical compositions typically should provide a dosage of from about 0.001 mg to about 2000 mg of compound per kilogram of body weight per day. Pharmaceutical dosage unit forms are prepared to provide from about 1 mg to about 1000 mg and preferably from about 10 to about 500 mg of the essential active ingredient or a
30 combination of essential ingredients per dosage unit form.

The active ingredient may be administered at once, or may be divided into a number of smaller doses to be administered at intervals of time by a suitable route, including orally, parenterally, rectally, topically and locally. It is understood that the precise dosage and duration of treatment is a function of the disease being treated and may be
35 determined empirically using known testing protocols or by extrapolation from *in vivo* or

in vitro test data. It is to be noted that concentrations and dosage values may also vary with the severity of the condition to be alleviated. It is to be further understood that for any particular subject, specific dosage regimens should be adjusted over time according to the individual need and the professional judgment of the person
5 administering or supervising the administration of the compositions, and that the concentration ranges set forth herein are exemplary only and are not intended to limit the scope or practice of the claimed compositions.

In instances in which the compounds exhibit insufficient solubility, methods for solubilizing compounds may be used. Such methods are known to those of skill in this
10 art, and include, but are not limited to, using co-solvents, such as dimethylsulfoxide (DMSO), using surfactants, such as TWEEN®, or dissolution in aqueous sodium bicarbonate. Derivatives of the compounds, such as prodrugs of the compounds may also be used in formulating effective pharmaceutical compositions.

Upon mixing or addition of the compound(s), the resulting mixture may be a
15 solution, suspension, emulsion or the like. The form of the resulting mixture depends upon a number of factors, including the intended mode of administration and the solubility of the compound in the selected carrier or vehicle. The effective concentration is sufficient for ameliorating the symptoms of the disease, disorder or condition treated and may be empirically determined.

20 The pharmaceutical compositions are provided for administration to humans and animals in unit dosage forms, such as tablets, capsules, pills, powders, granules, sterile parenteral solutions or suspensions, and oral solutions or suspensions, and oil-water emulsions containing suitable quantities of the compounds or pharmaceutically acceptable derivatives thereof. The pharmaceutically therapeutically
25 active compounds and derivatives thereof are typically formulated and administered in unit-dosage forms or multiple-dosage forms. Unit-dose forms as used herein refers to physically discrete units suitable for human and animal subjects and packaged individually as is known in the art. Each unit-dose contains a predetermined quantity of the therapeutically active compound sufficient to produce the desired therapeutic
30 effect, in association with the required pharmaceutical carrier, vehicle or diluent. Examples of unit-dose forms include ampoules and syringes and individually packaged tablets or capsules. Unit-dose forms may be administered in fractions or multiples thereof. A multiple-dose form is a plurality of identical unit-dosage forms packaged in a single container to be administered in segregated unit-dose form. Examples of
35 multiple-dose forms include vials, bottles of tablets or capsules or bottles of pints or

gallons. Hence, multiple dose form is a multiple of unit-doses that are not segregated in packaging.

Compositions for oral administration

5 Oral pharmaceutical dosage forms are either solid, gel or liquid. The solid dosage forms are tablets, capsules, granules, and bulk powders. Types of oral tablets include compressed, chewable lozenges and tablets which may be enteric-coated, sugar-coated or film-coated. Capsules may be hard or soft gelatin capsules, while granules and powders may be provided in non-effervescent or effervescent form with
10 the combination of other ingredients known to those skilled in the art. In certain embodiments, the formulations are solid dosage forms, preferably capsules or tablets. The tablets, pills, capsules, troches and the like can contain any of the following ingredients, or compounds of a similar nature: a binder; a diluent; a disintegrating agent; a lubricant; a glidant; a sweetening agent; and a flavoring agent.
15 Examples of binders include microcrystalline cellulose, gum tragacanth, glucose solution, acacia mucilage, gelatin solution, celluloses, polyvinyl pyrrolidone, povidone, croscopovidones, sucrose and starch paste. 30 propylene glycol monostearate, sorbitan monooleate, diethylene glycol monolaurate and polyoxyethylene laural ether.

In all embodiments, tablets and capsules formulations may be coated as known by those of skill in the art in order to modify or sustain dissolution of the active ingredient. If oral administration is desired, the compound could be provided in a
35 composition that protects it from the acidic environment of the stomach. Thus, for

example, they may be coated with a conventional enterically digestible coating, such as phenylsalicylate, waxes and cellulose acetate phthalate. Emetic-coatings also include fatty acids, fats, waxes, shellac, ammoniated shellac and cellulose acetate phthalates. Film coatings include hydroxyethylcellulose, sodium
5 carboxymethylcellulose, polyethylene glycol 4000 and cellulose acetate phthalate. The composition may also be formulated in combination with an antacid or other such ingredient.

When the dosage unit form is a capsule, it can contain, in addition to material of the above type, a liquid carrier such as a fatty oil. In addition, dosage unit forms can
10 contain various other materials which modify the physical form of the dosage unit, for example, coatings of sugar and other enteric agents. The compounds can also be administered as a component of an elixir, suspension, syrup, wafer, sprinkle, chewing gum or the like. A syrup may contain, in addition to the active compounds, sucrose as a sweetening agent and certain preservatives, dyes and colorings and flavors.
15 The active ingredient can also be mixed with other materials which do not impair the desired action, or with materials that supplement the desired action, such as antacids, H₂ blockers, and diuretics. The active ingredient is a compound or pharmaceutically acceptable derivative thereof as described herein.

Sugar-coated tablets are compressed tablets to which different layers of
20 pharmaceutically acceptable substances are applied. Film-coated tablets are compressed tablets which have been coated with a polymer or other suitable coating. Multiple compressed tablets are compressed tablets made by more than one compression cycle utilizing the pharmaceutically acceptable substances previously mentioned.

25 Liquid oral dosage forms include aqueous solutions, emulsions, suspensions, solutions and/or suspensions reconstituted from non-effervescent granules and effervescent preparations reconstituted from effervescent granules. Aqueous solutions include, for example, elixirs and syrups. Emulsions are either oil-in-water or water-in-oil.

30 Elixirs are clear, sweetened, hydroalcoholic preparations. Pharmaceutically acceptable carriers used in elixirs include solvents. Syrups are concentrated aqueous solutions of a sugar, for example, sucrose, and may contain a preservative. An emulsion is a two-phase system in which one liquid is dispersed in the form of small globules throughout another liquid. Pharmaceutically acceptable carriers used in
35 emulsions are non-aqueous liquids, emulsifying agents and preservatives.

Suspensions use pharmaceutically acceptable suspending agents and preservatives. Pharmaceutically acceptable substances used in non-effervescent granules, to be reconstituted into a liquid oral dosage form, include diluents, sweeteners and wetting agents. Pharmaceutically acceptable substances used in effervescent granules, to be reconstituted into a liquid oral dosage form, include organic acids and a source of carbon dioxide. Coloring and flavoring agents are used in all of the above dosage forms.

Solvents include glycerin, sorbitol, ethyl alcohol and syrup. Examples of preservatives include glycerin, methyl and propylparaben, benzoic acid, sodium benzoate and alcohol. Examples of non-aqueous liquids utilized in emulsions include mineral oil and cottonseed oil. Examples of emulsifying agents include gelatin, acacia, tragacanth, bentonite, and surfactants such as polyoxyethylene sorbitan monooleate. Suspending agents include sodium carboxymethylcellulose, pectin, tragacanth, Veegum and acacia. Diluents include lactose and sucrose. Sweetening agents include sucrose, syrups, glycerin and artificial sweetening agents such as saccharin. Wetting agents include propylene glycol monostearate, sorbitan monooleate, diethylene glycol monolaurate and polyoxyethylene lauryl ether. Organic acids include citric and tartaric acid. Sources of carbon dioxide include sodium bicarbonate and sodium carbonate. Coloring agents include any of the approved certified water-soluble FD and C dyes, and mixtures thereof. Flavoring agents include natural flavors extracted from plants such fruits, and synthetic blends of compounds which produce a pleasant taste sensation.

For a solid dosage form, the solution or suspension, in for example propylene carbonate, vegetable oils or triglycerides, is preferably encapsulated in a gelatin capsule. Such solutions, and the preparation and encapsulation thereof, are disclosed in U.S. Patent Nos. 4,328,245; 4,409,239; and 4,410,545. For a liquid dosage form, the solution, *e.g.*, for example, in a polyethylene glycol, may be diluted with a sufficient quantity of a pharmaceutically acceptable liquid carrier, *e.g.*, water, to be easily measured for administration.

Alternatively, liquid or semi-solid oral formulations may be prepared by dissolving or dispersing the active compound or salt in vegetable oils, glycols, triglycerides, propylene glycol esters (*e.g.*, propylene carbonate) and other such carriers, and encapsulating these solutions or suspensions in hard or soft gelatin capsule shells. Other useful formulations include those set forth in U.S. Patent Nos. Re 28,819 and 4,358,603. Briefly, such formulations include, but are not limited to,

those containing a compound provided herein, a dialkylated mono- or poly-alkylene glycol, including, but not limited to, 1,2-dimethoxymethane, diglyme, triglyme, tetraglyme, polyethylene glycol-350-dimethyl ether, polyethylene glycol-550-dimethyl ether, polyethylene glycol-750-dimethyl ether wherein 350, 550 and 750 refer to the approximate average molecular weight of the polyethylene glycol, and one or more antioxidants, such as butylated hydroxytoluene (BHT), butylated hydroxyanisole (BHA), propyl gallate, vitamin E, hydroquinone, hydroxycoumarins, ethanolamine, lecithin, cephalin, ascorbic acid, malic acid, sorbitol, phosphoric acid, thiodipropionic acid and its esters, and dithiocarbamates.

Alcohols used in these formulations are any pharmaceutically acceptable water-miscible solvents having one or more hydroxyl groups, including, but not limited to, propylene glycol and ethanol. Acetals include, but are not limited to, di(lower alkyl) acetals of lower alkyl aldehydes such as acetaldehyde diethyl acetal.

Injectables, solutions and emulsions

Parenteral administration, generally characterized by injection, either subcutaneously, intramuscularly or intravenously is also contemplated herein.

Isotonic agents include sodium chloride and dextrose. Buffers include phosphate and citrate. Antioxidants include sodium bisulfate. Local anesthetics include procaine hydrochloride. Suspending and dispersing agents include sodium carboxymethylcellulose, hydroxypropyl methylcellulose and polyvinylpyrrolidone. Emulsifying agents include Polysorbate 80 (TWEEN® 80). A sequestering or chelating agent of metal ions include EDTA. Pharmaceutical carriers also include ethyl alcohol, polyethylene glycol and propylene glycol for water miscible vehicles and sodium hydroxide, hydrochloric acid, citric acid or lactic acid for pH adjustment.

The concentration of the pharmaceutically active compound is adjusted so that an injection provides an effective amount to produce the desired pharmacological effect. The exact dose depends on the age, weight and condition of the patient or animal as is known in the art.

The unit-dose parenteral preparations are packaged in an ampoule, a vial or a syringe with a needle. All preparations for parenteral administration must be sterile, as is known and practiced in the art.

The compound may be suspended in micronized or other suitable form or may be derivatized to produce a more soluble active product or to produce a prodrug. The form of the resulting mixture depends upon a number of factors, including the intended mode of administration and the solubility of the compound in the selected carrier or vehicle. The effective concentration is sufficient for ameliorating the symptoms of the condition and may be empirically determined.

Lyophilized powders

Of interest herein are also lyophilized powders, which can be reconstituted for administration as solutions, emulsions and other mixtures. They may also be reconstituted and formulated as solids or gels.

5 The sterile, lyophilized powder is prepared by dissolving a compound provided herein, or a pharmaceutically acceptable derivative thereof, in a suitable solvent. The solvent may contain an excipient which improves the stability or other pharmacological component of the powder or reconstituted solution, prepared from the powder. Excipients that may be used include, but are not limited to, dextrose, sorbitol, fructose,
10 corn syrup, xylitol, glycerin, glucose, sucrose or other suitable agent. The solvent may also contain a buffer, such as citrate, sodium or potassium phosphate or other such buffer known to those of skill in the art at, typically, about neutral pH. Subsequent sterile filtration of the solution followed by lyophilization under standard conditions known to those of skill in the art provides the desired formulation. Generally, the
15 resulting solution will be apportioned into vials for lyophilization. Each vial will contain a single dosage (10-1000 mg, preferably 100-500 mg) or multiple dosages of the compound. The lyophilized powder can be stored under appropriate conditions, such as at about 4 °C to room temperature.

Reconstitution of this lyophilized powder with water for injection provides a
20 formulation for use in parenteral administration. For reconstitution, about 1-50 mg, preferably 5-35 mg, more preferably about 9-30 mg of lyophilized powder, is added per mL of sterile water or other suitable carrier. The precise amount depends upon the selected compound. Such amount can be empirically determined.

25 Topical administration

Topical mixtures are prepared as described for the local and systemic administration. The resulting mixture may be a solution, suspension, emulsions or the like and are formulated as creams, gels, ointments, emulsions, solutions, elixirs, lotions, suspensions, tinctures, pastes, foams, aerosols, irrigations, sprays,
30 suppositories, bandages, dermal patches or any other formulations suitable for topical administration.

The compounds or pharmaceutically acceptable derivatives thereof may be formulated as aerosols for topical application, such as by inhalation (see, e.g., U.S. Patent Nos. 4,044,126, 4,414,209, and 4,364,923, which describe aerosols for delivery
35 of a steroid useful for treatment of inflammatory diseases, particularly asthma). These

formulations for administration to the respiratory tract can be in the form of an aerosol or solution for a nebulizer, or as a microfine powder for insufflation, alone or in combination with an inert carrier such as lactose. In such a case, the particles of the formulation will typically have diameters of less than 50 microns, preferably less than 10 microns.

The compounds may be formulated for local or topical application, such as for topical application to the skin and mucous membranes, such as in the eye, in the form of gels, creams, and lotions and for application to the eye or for intracisternal or intraspinal application. Topical administration is contemplated for transdermal delivery and also for administration to the eyes or mucosa, or for inhalation therapies. Nasal solutions of the active compound alone or in combination with other pharmaceutically acceptable excipients can also be administered.

These solutions, particularly those intended for ophthalmic use, may be formulated as 0.01% - 10% isotonic solutions, pH about 5-7, with appropriate salts.

15

Tablets and capsules for rectal administration are manufactured using the same pharmaceutically acceptable substance and by the same methods as for formulations for oral administration.

25

Targeted Formulations

The compounds provided herein, or pharmaceutically acceptable derivatives thereof, may also be formulated to be targeted to a particular tissue, receptor, or other area of the body of the subject to be treated. Many such targeting methods are well
30 known to those of skill in the art. All such targeting methods are contemplated herein for use in the instant compositions. For non-limiting examples of targeting methods, see, e.g., U.S. Patent Nos. 6,316,652, 6,274,552, 6,271,359, 6,253,872, 6,139,865, 6,131,570, 6,120,751, 6,071,495, 6,060,082, 6,048,736, 6,039,975, 6,004,534, 5,985,307, 5,972,366, 5,900,252, 5,840,674, 5,759,542 and 5,709,874.

In one embodiment, liposomal suspensions, including tissue-targeted liposomes, such as tumor-targeted liposomes, may also be suitable as pharmaceutically acceptable carriers. Briefly, liposomes such as multilamellar vesicles (MLV's) may be formed by drying down egg phosphatidyl choline and brain phosphatidyl serine (7:3 molar ratio) on the inside of a flask. A solution of a compound provided herein in phosphate buffered saline lacking divalent cations (PBS) is added and the flask shaken until the lipid film is dispersed. The resulting vesicles are washed
10 to remove unencapsulated compound, pelleted by centrifugation, and then resuspended in PBS.

Articles of manufacture

The compounds or pharmaceutically acceptable derivatives may be packaged
15 as articles of manufacture comprising packaging material, a compound or composition, or pharmaceutically acceptable derivative thereof provided herein, and a label that indicates that the compound or composition, or pharmaceutically acceptable derivative thereof, is used for modulating the activity of a steroid nuclear receptor, or for treatment, prevention or amelioration of one or more symptoms of a steroid nuclear
20 receptor mediated diseases or disorder, or diseases or disorders in which steroid nuclear activity is implicated.

In another embodiment, the compounds for use in the compositions and methods provided are set forth in Table I.

C. EVALUATION OF THE ACTIVITY OF THE COMPOUNDS

Standard physiological, pharmacological and biochemical procedures are available for testing the compounds to identify those that possess biological activities that selectively modulate the activity of steroid nuclear receptors. Such assays include, for example, biochemical assays such as binding assays, fluorescence polarization assays, fluorescence resonance energy transfer (FRET) based coactivator recruitment assays (see generally Glickman *et al.*, *J. Biomolecular Screening*, 7 (1): 3-10 (2002)), as well as cell based assays including the co-transfection assay, the use of LBD-Gal 4 chimeras and protein-protein interaction assays (see, Lehmann. *et al.*, *J. Biol Chem.*, 272(6): 3137-3140 (1997).

High throughput screening systems are commercially available (see, *e.g.*, Zymark Corp., Hopkinton, MA; Air Technical Industries, Mentor, OH; Beckman Instruments Inc., Fullerton, CA; Precision Systems, Inc., Natick, MA) that enable these assays to be run in a high throughput mode. These systems typically automate entire procedures, including all sample and reagent pipetting, liquid dispensing, timed incubations, and final readings of the microplate in detector(s) appropriate for the

assay. These configurable systems provide high throughput and rapid start up as well as a high degree of flexibility and customization. The manufacturers of such systems provide detailed protocols for various high throughput systems. Thus, for example, Zymark Corp. provides technical bulletins describing screening systems for detecting
5 the modulation of gene transcription, ligand binding, and the like.

Assays that do not require washing or liquid separation steps are preferred for such high throughput screening systems and include biochemical assays such as fluorescence polarization assays (see for example, Owicki, J., *Biomol Screen* 2000 Oct;5(5):297) scintillation proximity assays (SPA) (see for example, Carpenter *et al.*,
10 *Methods Mol Biol* 2002;190:31-49) and FRET or time resolved FRET based coactivator recruitment assays (Mukherjee *et al.*, *J Steroid Biochem Mol Biol* 2002 Jul;81(3):217-25; (Zhou *et al.*, *Mol Endocrinol.* 1998 Oct;12(10):1594-604). Generally such assays can be performed using either the full length receptor, or fragment including the isolated LBD. In the case of the mineralocorticoid receptor, a useful fragment
15 comprises amino acids 671-984 of the full length sequence.

If a fluorescently labeled ligand is available, fluorescence polarization assays provide a way of detecting binding of compounds to the nuclear receptor of interest by measuring changes in fluorescence polarization that occur as a result of the displacement of a trace amount of the label ligand by the compound. Additionally this
20 approach can also be used to monitor the ligand dependent association of a fluorescently labeled coactivator peptide to the nuclear receptor of interest to detect ligand binding to the nuclear receptor of interest.

The ability of a compound to bind to a receptor, or heterodimer complex with RXR, can also be measured in a homogeneous assay format by assessing the degree
25 to which the compound can compete off a radiolabelled ligand with known affinity for the receptor using a scintillation proximity assay (SPA). In this approach, the radioactivity emitted by a radiolabelled compound generates an optical signal when it is brought into close proximity to a scintillant such as a Ysi-copper containing bead, to which the nuclear receptor is bound. If the radiolabelled compound is displaced from
30 the nuclear receptor the amount of light emitted from the nuclear receptor bound scintillant decreases, and this can be readily detected using standard microplate liquid scintillation plate readers such as, for example, a Wallac MicroBeta reader. The ability of a compound to effect a ligand dependent interaction of a co-activator peptide with a nuclear receptor can also be assessed by fluorescence resonance
35 energy transfer (FRET), or time resolved FRET, in order to characterize the agonist or

antagonist activity of the compounds disclosed herein. Both approaches rely upon the fact that energy transfer from a donor molecule to an acceptor molecule only occurs when donor and acceptor are in close proximity. Typically the assay in this case involves the use a recombinant Glutathione-S-transferase (GST)-nuclear receptor
5 ligand binding domain (LBD) fusion protein and a synthetic biotinylated peptide sequenced derived from the receptor interacting domain of a co-activator peptide such as the steroid receptor coactivator 1 (SRC-1). Typically, GST-LBD is labeled with a europium chelate (donor) via a europium-tagged anti-GST antibody, and the coactivator peptide is labeled with allophycocyanin via a streptavidin-biotin linkage.

10 In the presence of an agonist for the nuclear receptor, the peptide is recruited to the GST-LBD bringing europium and allophycocyanin into close proximity to enable energy transfer from the europium chelate to the allophycocyanin. Upon excitation of the complex with light at 340 nm excitation energy absorbed by the europium chelate is transmitted to the allophycocyanin moiety resulting in emission at 665 nm. If the
15 europium chelate is not brought in to close proximity to the allophycocyanin moiety there is little or no energy transfer and excitation of the europium chelate results in emission at 615 nm. Thus the intensity of light emitted at 665 nm gives an indication of the strength of the protein-protein interaction. The activity of a nuclear receptor antagonist can be measured by determining the ability of a compound to competitively
20 inhibit (*i.e.*, IC₅₀) the activity of an agonist for the nuclear receptor.

In addition a variety of cell based assay methodologies may be successfully used in screening assays to identify and profile the specificity of compounds of the present invention. These approaches include transfection assays, translocation
25 assays, complementation assays and the use of gene activation technologies to over express endogenous nuclear receptors.

The basic co-transfection assay is based on the co-transfection into the cell of an expression plasmid to produce the nuclear receptor of interest in the cell with a reporter plasmid comprising a reporter gene whose expression is under the control of a hormone response element that is capable of interacting with that nuclear receptor.
30 (See for example US Patents Nos. 5,071,773; 5,298,429, 6,416,957, WO 00/76523). Treatment of the transfected cells with an agonist for the nuclear receptor increases the transcriptional activity of that receptor which is reflected by an increase in expression of the reporter gene, which may be measured by a variety of standard procedures.

In one embodiment of this method, the host cell endogenously expresses the nuclear receptor and appropriate co-factors or heterodimeric partners. Typically, such a situation may occur with a primary cell or cell lines derived directly from a primary cell type, is used to characterize compounds of the present invention. Accordingly creation
5 of the assay system requires only the transfection into the cell of a suitable reporter gene(s) as are described herein.

A cell line that endogenously expresses the MR includes, for example, the mouse collecting duct cell line described in Am. J. Physiol. Endocrinol Metab. 279 E386-E394 (2000). Alternatively the expression of endogenous genes (detected via RT-
10 PCR) can be used to monitor MR transcriptional activity in response to the addition of a test compound.

In another aspect, the host cell may lack sufficient endogenous expression of a suitable nuclear receptor, in which case one may be introduced by transfection of the cell line with an expression plasmid, as described below. Typically, the expression
15 plasmid comprises: (1) a promoter, such as an SV40 early region promoter, HSV tk promoter or phosphoglycerate kinase (pgk) promoter, CMV promoter, Sr α promoter or other suitable control elements known in the art, (2) a cloned polynucleotide sequence, such as a cDNA encoding a receptor, co-factor, or a fragment thereof, ligated to the promoter in sense orientation so that transcription from the promoter will produce a
20 RNA that encodes a functional protein, and (3) a polyadenylation sequence. As an example not to be construed as a limitation, an expression cassette of the invention may comprise the cDNA expression cloning vectors, or other preferred expression vectors known and commercially available from vendors such as Invitrogen, (CA), Stratagene, (CA) or Clontech, (CA). Alternatively expression vectors developed by
25 academic groups such as the pCMX vectors originally developed in the Evans lab (Willey et al. Genes & Development (1995) 9:1033-1045) may also be used. The transcriptional regulatory sequences in an expression cassette are selected by the practitioner based on the intended application; depending upon the specific use, transcription regulation can employ inducible, repressible, constitutive, cell-type
30 specific, developmental stage-specific, sex-specific, or other desired type of promoter or control sequence.

Alternatively, the expression plasmid may comprise an activation sequence to activate or increase the expression of an endogenous chromosomal sequence. Such activation sequences include for example, a synthetic zinc finger motif (for example
35 see US Patents 6,534,261 and 6,503,7171) or a strong promoter or enhancer

sequence together with a targeting sequence to enable homologous or non-homologous recombination of the activating sequence upstream of the gene of interest.

5 In one aspect of these methods, chimeras are used in place of the full-length nuclear receptor. Such chimeras typically comprise the ligand binding domain and hinge region of the nuclear receptor coupled to a heterologous DNA binding domain (DBD).

10 Typically for such chimeric constructs, heterologous DNA binding domains from distinct, well-defined nuclear receptors are used, or alternatively the DNA binding domains from yeast or bacterially derived transcriptional regulators such as members of the GAL 4 and Lex A (GenBank accession number ILEC) / Umod super families may be used.

GAL4 (GenBank Accession Number P04386,) is a positive regulator for the expression of the galactose-induced genes. (see for example, Keegan et al., Science 15 231: 699-704 (1986)). Preferably the first 96 amino acids of the Gal4 protein are used, most preferably the first 147 amino acid residues of yeast Gal4 protein are used. For those receptors that can function as heterodimers with RXR, the method typically includes the use of expression plasmids for both the nuclear receptor of interest and RXR. Such sequences include, but are not limited to the following members of the 20 RXR gene family, including RXR α , (GenBank Accession No. NM_002957), RXR β (GenBank Accession No. XM_042579) and RXR γ (GenBank Accession No. XM_053680).

To identify compounds that act to modulate co-factor, or nuclear receptor heterodimerization, a mammalian two-hybrid assay can be used (see, for example, US 25 Patent Nos. US 5,667,973, 5,283,173 and 5,468,614). This approach identifies protein-protein interactions in vivo through reconstitution of a strong transcriptional activator upon the interaction of two proteins, a "bait" and "prey" (Fields S and Song O (1989) Nature 340: 245; Willey et al., (1995) Gene & Development 9 1033-1045). This system relies on functional dimeric interactions between two fusion proteins, one 30 carrying the GAL4 DNA-binding domain fusion with the ability to bind to a GAL4_{UAS}-containing reporter gene. The other carries the VP16 transactivation domain fusion. When expressed together, DNA binding and transcriptional activation is reconstituted in a single complex. Functional interaction, for example between a GAL-SRC-1 fusion protein and VP16-VDR fusion protein should lead to constitutive activation of a

suitable reporter plasmid, such as luciferase reporter construct comprising GAL4 upstream Activating Sequences (UAS).

Such reporter plasmids may be constructed using standard molecular biological techniques by placing cDNA encoding for the reporter gene downstream from a
5 suitable minimal promoter. For example luciferase reporter plasmids may be constructed by placing cDNA encoding firefly luciferase (typically with SV40 small t intron and poly-A tail, (de Wet et al., (1987) Mol. Cell. Biol. 7 725-735) down stream from the herpes virus thymidine kinase promoter (located at nucleotides residues-105 to +51 of the thymidine kinase nucleotide sequence, pBLCAT2 (Luckow & Schutz
10 (1987) Nucl. Acid. Res. 15 5490-5494)) which is linked in turn to the appropriate response elements.

Transactivation domains are well known in the art and can be readily identified by the artisan. Examples include the GAL4 activation domain, TAT, VP16, and analogs thereof.

15 Response elements (RE) are well known and have been thoroughly described in the art. Such response elements can include direct repeat structures or inverted repeat structures based on well defined hexad half sites, as described in greater detail below. Exemplary hormone response elements are composed of at least one direct repeat of two or more half sites, separated by a spacer having in the range of 0 up to 6
20 nucleotides. The spacer nucleotides can be randomly selected from any one of A, C, G or T. Each half site of response elements contemplated for use in the practice of the invention comprises the sequence: -RGBNNM-, wherein R is selected from A or G; B is selected from G, C, or T; each N is independently selected from A, T, C, or G; and M is selected from A or C; is with the proviso that at least 4 nucleotides of said -
25 RGBNNM- sequence are identical with the nucleotides at corresponding positions of the sequence -AGGTCA-. Response elements employed to profile the compounds of the present invention can optionally be preceded by N, wherein x falls in the range of 0 up to 5. Preferred response elements useful in the methods of the present invention include hormone response elements such as the Glucocorticoid response element
30 (GRE), for example as found in the MMTV LTR.

The choice of hormone response element is dependent upon the type of assay to be used. In the case of the use of a cell line endogenously expressing a steroid receptor, a known steroid RE would typically be used. In the case of a MR-LBD-Gal4 fusion, a GAL4 UAS would be used. Typically the GAL4 UAS would comprise the

sequence 5'CGGRNNRCYNYNCNCCG-3', where Y = C or T, R = A or G, and N = A, C, T or G, and would be present as a tandem repeat of 4 copies.

Numerous reporter gene systems are known in the art and include, for example, alkaline phosphatase (see, Berger, J., *et al.*, *Gene* (1988), Vol. 66, pp. 1-10; and Kain, S.R., *Methods. Mol. Biol.* (1997), Vol. 63, pp. 49-60), β -galactosidase (See, U.S. Patent No. 5,070,012, issued Dec, 3, 1991 to Nolan *et al.*, and Bronstein, I., *et al.*, *J. Chemilum. Biolum.* (1989), Vol. 4, pp. 99-111), chloramphenicol acetyltransferase (See, Gorman *et al.*, *Mol. Cell Biol.* (1982), Vol. 2, pp. 1044-51), β -glucuronidase, peroxidase, β -lactamase (U.S. Patent Nos. 5,741,657 and 5,955,604), catalytic antibodies, luciferases (U.S. Patents 5,221,623; 5,683,888; 5,674,713; 5,650,289; and 5,843,746) and naturally fluorescent proteins (Tsien, R.Y., *Annu. Rev. Biochem.* (1998), Vol. 67, pp. 509-44).

Numerous methods of co-transfecting the expression and reporter plasmids are known to those of skill in the art and may be used for the co-transfection assay to introduce the plasmids into a suitable cell type.

Any compound which is a candidate for the modulation of a steroid nuclear receptor activity may be tested by these methods. Generally, compounds are tested at several different concentrations to optimize the chances that modulation of receptor activity will be detected and recognized if present. Typically assays are performed in triplicate or quadruplicate and vary within experimental error by less than 15%. Each experiment is typically repeated three or more times with similar results.

Activity of the reporter gene can be conveniently normalized to the internal control and the data plotted as fold activation relative to untreated cells. A positive control compound (agonist) may be included along with DMSO as high and low controls for normalization of the assay data. Similarly, antagonist activity can be measured by determining the ability of a compound to competitively inhibit the activity of an agonist.

Additionally, the compounds and compositions can be evaluated for their ability to increase or decrease the expression of genes known to be modulated by a steroid nuclear receptor and other nuclear receptors *in vivo*, using Northern-blot, RT PCR or oligonucleotide microarray analysis to analyze RNA levels. Western-blot analysis can be used to measure expression of proteins encoded by mineralocorticoid receptor target genes. Genes that are known or suspected to be regulated by the mineralocorticoid receptor, for example, include; *sgk* (serum and glucocorticoid

regulated kinase (NM_005627)), Na/K ATPase, $\alpha 1, \beta 1$ subunits, ENaC α (epithelial Na channel (NM_001038)), GILZ (glucocorticoid induced leucine zipper (BC 061979)), and NDRG2, (N-myc downstream regulated gene 2 (NM_016250)).

Established animal models exist and these can be used to further profile and
5 characterize the claimed compounds. These model systems for MR include the
Kagawa bioassay of urinary electrolytes (Bhargava et al., Endocrinology 142(4): 1587-
94, (2001)), the Goldblatt model (Nicoletti et al., Hypertension 26(1): 101-11, (1995)),
the Cardiac fibrosis model described in Ramires et al., (J. Mol. Cell. Cardiol. Mar;30
(3):475-83, (1998)), the Renal vascular injury in SHRSP saline-drinking stroke-prone
10 spontaneously hypertensive rats described in Rocha et al., (Hypertension 33 (1 Pt 2):
232-7, (1999)), and Rodent model of myocardial necrosis and renal arteriopathy
described in Rocha et al., (Endocrinology Oct;141(10):3871-8 (2000)).

F. PREPARATION OF THE COMPOUNDS OF THE INVENTION

Starting materials in the synthesis examples provided herein are either available from commercial sources or via literature procedures (e.g., March *Advanced Organic Chemistry: Reactions, Mechanisms, and Structure*, (1992) 4th Ed.; Wiley

Interscience, New York). All commercially available compounds were used without further purification unless otherwise indicated. CDCl₃ (99.8% D, Cambridge Isotope Laboratories) was used in all experiments as indicated. Proton (¹H) nuclear magnetic resonance (NMR) spectra were recorded on a Bruker Avance 400 MHz NMR spectrometer. Significant peaks are tabulated and typically include: number of protons, and multiplicity (s, singlet; d, double; t, triplet; q, quartet; m, multiplet; br s, broad singlet). Chemical shifts are reported as parts per million (δ) relative to tetramethylsilane. Low resolution mass spectra (MS) were obtained as electrospray ionization (ESI) mass spectra, which were recorded on a Perkin-Elmer SCIEX HPLC/MS instrument using reverse-phase conditions (acetonitrile/water, 0.05% trifluoroacetic acid). Flash chromatography was performed using Merck Silica Gel 60 (230-400 mesh) following standard protocol (Still *et al.* (1978) *J. Org. Chem.* 43:2923). It is understood that in the following description, combinations of substituents and/or variables of the depicted formulae are permissible only if such contributions result in stable compounds under standard conditions.

It will also be appreciated by those skilled in the art that in the process described below the functional groups of intermediate compounds may need to be protected by suitable protecting groups. Such functional groups include hydroxy, amino, mercapto and carboxylic acid. Suitable protecting groups for hydroxy include trialkylsilyl or diarylalkylsilyl (e.g., *t*-butyldimethylsilyl, *t*-butyldiphenylsilyl or trimethylsilyl), tetrahydropyranyl, benzyl, and the like. Suitable protecting groups for amino, amidino and guanidino include *t*-butoxycarbonyl, benzyloxycarbonyl, and the like. Suitable protecting groups for mercapto include -C(O)-R (where R is alkyl, aryl or aralkyl), *p*-methoxybenzyl, trityl and the like. Suitable protecting groups for carboxylic acid include alkyl, aryl or aralkyl esters.

Protecting groups may be added or removed in accordance with standard techniques, which are well-known to those skilled in the art and as described herein. The use of protecting groups is described in detail in Green, T.W. and P.G.M. Wutz, *Protective Groups in Organic Synthesis* (1991), 2nd Ed., Wiley-Interscience. One of ordinary skill in the art could easily ascertain which choices for each substituent are possible for the reaction conditions of each Scheme. Moreover, the substituents are selected from components as indicated in the specification heretofore, and may be attached to starting materials, intermediates, and/or final products according to schemes known to those of ordinary skill in the art.

Also it will be apparent that many of the products could exist as one or more isomers, that is E/Z isomers, enantiomers and/or diastereomers.

Compounds of formula (I) may be prepared as depicted in Scheme 1. In general acylation of a primary or secondary amine, R^6R^7NH , with a pyrrole-3-carboxylic acid chloride under basic conditions and with heating can yield a pyrrole amide of formula (I). For example, a primary heteroaryl amine can be acylated with this acid chloride to afford the corresponding amide (I), wherein R^6 is hydrogen and R^7 is heteroaryl.

Scheme 1. General synthesis of compounds of formula (I).

10

Furthermore, a substituted aniline, such as $[(R^{26})(R^{25})_mPhN(R^6)H]$, can react with a pyrrole-3-carboxylic acid chloride in a manner as described above to yield the corresponding pyrrole product of formula (Ib), equivalent to formula (I) wherein R^7 is a substituted phenyl.

15

Compounds of formula (Ib) and analogous compounds of formula (I) in which R^7 is substituted aryl or heteroaryl also may be synthesized under alternate conditions as shown in Scheme 2.

20

Scheme 2. Preparation of compounds of formula (Ib).

In general, an amine (R^6NH_2) can react with a pyrrole-3-carboxylic acid chloride under basic conditions to yield the corresponding carboxamide. This amide intermediate can then react with an aryl (or heteroaryl) bromide (chloride, iodide, triflate or tosylate) such as, for example, substituted bromobenzene under copper- or palladium-mediated conditions to give the corresponding product of formula (Ib), equivalent to formula (I) wherein R^7 is substituted phenyl. The synthetic methodology can be adapted from one of the highly general and robust conditions for transition metal-catalyzed amidations that have been reported by Buchwald (*J. Am. Chem. Soc.* **2002**, 124, 7421-7428; *Org. Lett.* **2000**, 2, 1101-1104).

In general, a pyrrole-3-carboxylic acid chloride may be prepared as depicted in Scheme 3.

Scheme 3. General synthesis of a pyrrole-3-carboxylic acid chloride.

A haloketone ($X = \text{halo}$) can be reacted with a β -ketoester under basic conditions such as, for example, sodium hydride in THF, to yield the corresponding 1,4-diketone. This diketone intermediate can be condensed with a primary amine (R^4NH_2) such as, for example, where R^4 is aryl or heteroaryl, under acidic conditions and with heating to afford the respective pyrrole-3-carboxylic acid ester. This intermediate ester can then be converted into its corresponding acid chloride under typical conditions such as, for example, by first hydrolysis with 2N NaOH in methanol and followed by treatment with oxalyl chloride in DCM. Likewise, other types of primary amines such as, for example, benzyl amines (aralkyl) can be utilized in the reaction sequence to provide the corresponding pyrrole intermediates wherein R^4 is benzyl.

Other pyrrole-3-carboxylic acid chlorides, such as wherein $R^1 = R^2$ and $R^3 = H$, may be synthesized as shown in Scheme 4.

Scheme 4. Preparation of other pyrrole-3-carboxylic acid chlorides.

5

Thus, for example, a primary amine (R^4NH_2) and a symmetric 1,4-diketone can be condensed under Paal-Knorr conditions to yield the corresponding 2,5-disubstituted pyrrole, which can be converted to its pyrrole-3-carboxaldehyde under typical conditions such as, for example, Vilsmeier-Haack formulation. This intermediate aldehyde can then be oxidized to the corresponding carboxylic acid under conditions such as, for example, aqueous $KMnO_4$ in acetone. Next, the acid intermediate can be converted to its corresponding acid chloride under typical conditions.

10

Products of formula (I) in which R^1 is NH_2 , equivalent to 2-aminopyrroles (Ic), may be prepared as depicted in Scheme 5. This reaction sequence has been described in previous literature (WO 03/027069). First, alkylation of a cyanoacetamide such as, for example, where R^7 is substituted phenyl, with a bromoketone in the presence of a base, e.g. NaOMe in methanol, can yield the corresponding diketone intermediate. A mixture of the diketone and a primary amine, R^4NH_2 , can be heated under acidic conditions to afford the 2-aminopyrrole product of formula (Ic).

15

20

Scheme 5. Preparation of compounds of formula (Ic).

This 2-aminopyrrole (Ic) can be converted subsequently to other products, of which some sample reactions are depicted in Scheme 6.

Scheme 6. Representative compounds derived from 2-aminopyrroles (Ic).

5

For example, treatment with an electrophile such as an acid chloride or isocyanate under basic conditions can yield the corresponding amide or urea, respectively. Alternatively, diazotization of the 2-aminopyrrole can provide the diazonium salt, which can be converted to its 2-halopyrrole or 2-cyanopyrrole under Sandmeyer conditions. Subsequently, the 2-halopyrrole can undergo other transition metal-catalyzed reactions such as aryl-aminations, aryl-amidations, Ullman ether syntheses and cross-coupling reactions (e.g. Heck, Negishi, Suzuki and Sonogashira). For example, treatment with amines or alcohols under suitable conditions promoted by a palladium catalyst can yield aryl amines (Y = NR) or ethers (Y = O). Also the 2-halopyrrole may undergo carbonylation reactions to provide the corresponding pyrrole-2-carboxylic acid esters. These transformations represent a sampling of the many reactions that can be conceived for these 2-aminopyrroles.

Pyrrole compounds of formula (II) may be prepared as depicted in Scheme 7. First, an appropriate ketone can be alkylated with a halo-ketoester under basic conditions to give the corresponding 2,5-diketoester. This diketoester intermediate can react with an amine (R^5NH_2) under Paal-Knorr conditions to yield the corresponding pyrrole-2-carboxylic ester. Then this ester intermediate can be converted subsequently to the corresponding amide of formula (II) under conditions previously described.

Scheme 7. Preparation of compounds of formula (II).

25 Thus, for example, a ketone wherein R^4 is substituted phenyl can be alkylated with ethyl 3-bromo-2-ketopyruvate ($R^3 = H$) to yield the corresponding 2,5-diketoester. This diketoester intermediate can be condensed with an amine such as an alkyl amine to provide the corresponding pyrrole-2-carboxylic ester, in which R^5 is alkyl. This ester intermediate can be converted to its acid chloride and then condensed with an amine, such as a heteroaryl amine, to afford the product of formula (IIb), equivalent to formula (II) wherein R^4 is substituted phenyl and R^7 is heteroaryl.

30

Compounds of formula (III) may be prepared as depicted in Scheme 8. Here, a haloketone can react with a β -ketoester under basic conditions to yield a 1,4-diketone. The diketone intermediate can be condensed as described previously with an amine, R^5NH_2 , to provide the corresponding pyrrole-3-carboxylic acid ester. Next this ester intermediate can be converted to its acid chloride and then condensed with an amine, $R^6(R^7)NH$, to afford the product of formula (III).

35

Scheme 8. General preparation of compounds of formula (III).

Thus, for example, ethyl acetoacetate can be alkylated with a haloketone such as
 5 where R^4 is substituted phenyl to give the corresponding diketone. Under Paal-Knorr
 conditions this diketone can be condensed with an alkyl amine to yield the appropriate
 pyrrole-3-carboxylic acid ester, which can be converted to its acid chloride and then
 condensed with an amine, such as heteroaryl amine, to afford the product of formula
 (IIIb), equivalent to formula (III) wherein R^4 is substituted phenyl and R^7 is heteroaryl.

10

Other compounds of formula (III), such as where $R^3 = H$, may be prepared as depicted
 in Scheme 9. Here a haloketone can react with a cyanoacetate ester under basic
 conditions to yield the corresponding γ -ketoester. The ketoester intermediate can then
 15 be reductively cyclized under conditions such as with Raney-Ni and formic acid to
 provide the corresponding pyrroline-3-carboxylic acid ester. This ester intermediate
 can be oxidized under conditions such as via transfer hydrogenation with 10% Pd/C to
 give the corresponding pyrrole, which can be alkylated with a suitable electrophile,
 R^5X . The resulting pyrrole-3-carboxylic acid ester can be converted to an amide of
 20 formula (IIIc) as previously described. For example, methyl cyanoacetate can be
 alkylated with a haloketone, e.g. R^4 is substituted heteroaryl, to give the corresponding
 2-cyano-4-ketoester. This ester intermediate can be converted to its pyrrole-3-
 carboxylic acid methyl ester as described previously and then alkylated by sequential
 treatment with a base, e.g. sodium hydride, and then a suitable electrophile, e.g. alkyl

bromide. The resulting ester can be converted to its acid chloride and then treated with an amine, such as a substituted aniline, to yield the corresponding product of formula (IIIc), equivalent to formula (III) wherein R^4 is substituted heteroaryl and R^7 is substituted phenyl.

5

Scheme 9. Synthesis of other pyrrole compounds of formula (IIIc).

Alternatively these analogues (IIIc) may be prepared as depicted in Scheme 10. Here, a pyrrole-3-carboxylic acid ester can be brominated under typical conditions, such as with NBS, to afford the corresponding 5-bromopyrrole intermediate. Subsequent treatment with base followed by a suitable electrophile (R^5X) can then yield the N-substituted pyrrole intermediate. Next, a cross-coupling reaction of an appropriate boronic acid and this intermediate under typical Suzuki conditions can provide the corresponding pyrrole intermediate, analogous to that shown in Scheme 9. Likewise, the resulting pyrrole-3-carboxylic acid ester can be converted to amides of formula (IIIc) as previously described. In addition the list of suitable boronic acids is quite extensive and can consist of examples, where R^4 can be alkyl, alkenyl, aryl, heteroaryl and several others.

10

15

Scheme 10. Alternate preparation of pyrrole compounds (IIIc).

Compounds of formula (III) in which R³ is OR⁹, equivalent to 2-alkoxypyrroles (IIId), may be prepared as depicted in Scheme 11. Here, a malonate diester can be alkylated with a suitable bromoketone under basic conditions, e.g. NaH in THF, to yield a ketodiester, which can be condensed with an amine (R⁵NH₂) under typical conditions to give the corresponding pyrrolinone-3-carboxylic acid ester. This pyrrolinone can be alkylated with a suitable electrophile under basic conditions and the resulting ester then can be converted to its amide of formula (IIId) under conditions previously described.

Scheme 11. Synthesis of pyrrole compounds of formula (IIId).

In addition, compounds of formula (III) in which R³ is YR⁹ may be prepared as depicted in Scheme 12. Here, the pyrrolinone-3-carboxylic acid ester, described previously in

Scheme 11, can be converted to an activated sulfonate such as by sequential treatment with a suitable base, e.g. NaH in THF, and then trifluoromethane-sulfonic anhydride. This pyrrole intermediate can then undergo transition metal-catalyzed reactions such as couplings with amines or thiols under appropriate conditions to yield the respective aryl amines and sulfides. Likewise, these intermediates can be converted to amides of formula (IIIe), equivalent to formula (III) wherein R^3 is an amine ($Y = NR^9$) or a sulfide ($Y = S$).

Scheme 12. Synthesis of pyrrole compounds of formula (IIIe).

Compounds of formula (III) also may be prepared as depicted in Scheme 13. Thus, for example, the triflate prepared in Scheme 12 can undergo Suzuki reactions such as with *B*-alkyl-9-BBN to afford the corresponding pyrrole, in which R^3 is alkyl. And other transition metal-catalyzed reactions can be envisaged for this substrate.

Scheme 13. Synthesis of pyrrole compounds of formula (III).

Similarly, compounds of formula (IV) may be prepared as depicted in Scheme 14. Here, a ketone can be alkylated with a halo-ketoester, e.g. ethyl bromopyruvate ($R^1 = H$), under basic conditions to yield the corresponding 2,5-diketoester. This diketoester intermediate can be condensed as described previously with an amine, $R^{32}NH_2$, to provide the corresponding pyrrole-2-carboxylic ester. Next, this ester intermediate can be converted to its acid chloride and then condensed with an amine to afford the product of formula (IV).

Scheme 14. Preparation of pyrrole compounds of formula (IV).

10

Also compounds of formula (IV) may be prepared as depicted in Scheme 15. Here, a pyrrole-2-carboxylic acid ester can undergo bromination under typical conditions such as with bromine in carbon tetrachloride to yield the corresponding 4-bromopyrrole ester. Next, this intermediate can undergo Suzuki cross-coupling reactions with boronic acids to provide the corresponding product esters, which can be converted to the final product amides as previously described. And other transition metal-catalyzed reactions can be envisaged for this substrate, such as Heck, Stille, aryl amination and amidation.

15

Scheme 15. Preparation of pyrrole compounds of formula (IV).

25

Schemes 1-15 depict the preparation of various pyrrole amide isomers (I-IV), many of which can be generated from commercially available amines, R^6R^7NH . In addition one skilled in the art of chemical synthesis should be familiar with numerous procedures reported for preparing amines in the literature. The following schemes focus on several reactions used for the synthesis of aryl and heteroaryl amines. In particular, the reaction schemes exemplify the preparation of amines bearing the following functional groups: ketone, sulfone, sulfonamide and ether. Multiple other modifications and syntheses can be envisaged for substituted aryl or heteroaryl amines. In general aliphatic amines are readily available from commercial sources. Also the preparation of aliphatic amines has been thoroughly documented in the literature and, thus, will not be elaborated herein.

As shown in Scheme 16, aminoaryl-ketones (V) can be prepared from acetanilides under Friedel-Crafts conditions [see *J. Med. Chem.* **1983**, 26, 96-100]. Thus, acetanilides can be acylated, for example, with aryl chlorides to yield acetamido-benzophenones in which R^{14} is substituted phenyl. Deprotection of the acetamides under typical conditions can provide the corresponding amino-benzophenones (V), which can be incorporated into amides of formulae (I-IV).

Scheme 16. Preparation of aminoaryl ketones (V).

Aminoaryl ketones (V) can also be prepared via organometallic intermediates as depicted in Scheme 17. Thus, for example, an aryl-lithium species can be generated from a bromo-acetanilide and then added to an acid chloride to yield the corresponding ketone. Subsequent deprotection under typical conditions can then provide the desired aminoaryl ketone (V). Alternatively, a suitable Weinreb amide can be treated with a Grignard reagent to afford the corresponding ketone, which can be deprotected similarly. These reaction sequences also can be applied to appropriate starting materials for preparation of the *ortho* and *meta* isomers.

Scheme 17. Alternate synthesis of aminoaryl ketones (V).

- Aminoaryl sulfones may be prepared from appropriately substituted fluoro-nitrobenzenes and sulfinic acid metal salts as depicted in Scheme 18. Thus, a 4-fluoro-nitrobenzene species can react, for example, with sodium methanesulfinate to afford the corresponding 4-methanesulfonyl-nitrobenzene. Reduction of the nitro intermediate under typical conditions such as tin chloride then provide the desired 4-methanesulfonyl-aniline (VI), which can be incorporated into amides of formulae (I-IV).
- Similar chemistries can be pursued for isomeric species as well as heteroaryl analogues such as that represented by the pyridine species (VII).

15

Scheme 18. Preparation of aminoaryl sulfones (VI) and pyridine analogues (VII).

Similarly, aminoaryl sulfones (VI) may be prepared as depicted in Scheme 19. Here, thiols or thiolates can react with activated aryl halides or heteroaryl halides to give the

corresponding sulfides, which can be oxidized under literature conditions such as with mCPBA to yield sulfone intermediates. Subsequent reduction of the nitro moiety under typical conditions, e.g. tin chloride, can provide the respective aryl or heteroaryl amine intermediate, which can be incorporated into amides of formulae (I-IV). Thus, for example, alkyl or aryl thiolates can undergo the reaction sequence with appropriately substituted fluoro-nitrobenzenes as described to yield the corresponding sulfones (VI), where R¹⁵ is alkyl or aryl, respectively. Similar chemistries can be pursued for other aryl or heteroaryl isomers, such as those derived from an *ortho*-fluoro species.

Scheme 19. Alternate synthesis of aminoaryl sulfones (VI).

Also, aryl and heteroaryl thiols may be substituted, e.g. alkylated with an alkyl bromide, and then converted to the corresponding sulfones (VI and VII) as shown in Scheme 20.

Scheme 20. Alternate synthesis of aminoaryl sulfones (VI).

Sulfonamides (VIII) may be prepared as depicted in Scheme 21. Here, various nitro-anilines can be diazotized under typical conditions and then converted directly to its corresponding sulfonyl chloride, for example, with sulfur dioxide and cuprous chloride under acidic conditions [US Pat. 4,456,469; UK Pat. Applic. GB 2,246,352 A; *J. Med. Chem.* **2003**, *46*, 1811-1823]. Subsequent treatment of the isolated sulfonyl chloride with an amine, (R¹⁴)₂NH, followed by reduction under typical conditions can yield the corresponding aminoaryl sulfonamide (VIII), which can be incorporated into amides of formulae (I-IV). Similar chemistries can be pursued for heteroaryl analogues by starting with the appropriate nitro-heteroarylamines.

Scheme 21. Preparation of aminoaryl sulfonamides (VIII).

5 Alternatively, aminoaryl sulfonamides (VIII) may be synthesized as depicted in Scheme 22. Here, nitroaryl-sulfonyl chlorides can be prepared from nitroaryl-sulfides by reaction with a chlorinating agent, for example chlorine, in a suitable solvent such as chloroform in the presence of water [UK Pat. Applic. GB 2,246,352 A]. The sulfonyl chloride can then be converted its aminoaryl sulfonamide as described previously.

10 Thus, for example, a nitroaryl halide can react with sodium benzylthiolate to afford the corresponding sulfide where R¹⁵ is benzyl. Next, this sulfide can be converted to its sulfonyl chloride, condensed with an amine and then reduced to yield the corresponding sulfonamide (VIII), which can be incorporated into amides of formulae (I-IV).

15 **Scheme 22.** Alternate synthesis of aminoaryl sulfonamides (VIII).

25

In addition, acetanilides can undergo chlorosulfonation under typical conditions, such as with chlorosulfonic acid [see, for example, *J. Med. Chem.* **2003**, *46*, 2187-2196], to yield chlorosulfonyl-acetanilides as shown in Scheme 23. Subsequently, the intermediate can be converted directly to the corresponding sulfonamides upon

30 treatment with an amine, HN(R¹⁴)₂. The aminoaryl sulfonamide product (VIII) can then be obtained upon deprotection of the acetamide under typical conditions.

35

Scheme 23. Alternate synthesis of aminoaryl sulfonamides (VIII).

20

Aminoaryl ethers (IX) may be prepared by either of the methods depicted in Scheme 24. In the first, for example, an alkoxide can react with an activated nitroaryl species such as a 4-fluoro-nitrobenzene to yield the corresponding alkyl nitrophenyl ether. This intermediate ether can then be reduced, such as via catalytic hydrogenation, to give an aminoaryl ether product (IX). Similar chemistries can be envisaged wherein the alkoxide is replaced by a phenoxide or heterocyclic analogue. Also, the nitroaryl species can be replaced by a halo-nitroheteroaromatic analogue. In the second sequence, for example, a nitro-phenol species can be substituted, e.g. alkylated with an alkyl bromide, and then reduced as previously described to afford the

25

corresponding aminoaryl ethers (IX). In addition, the nitro-phenol species can undergo substitution under Mitsunobu conditions with alcohols to yield similar alkyl nitrophenyl ethers, which can undergo reduction to give the corresponding ethers (IX). All of these aminoaryl ethers can subsequently be incorporated into amides of formulae (I-IV).

Scheme 24. Preparation of aminoaryl ethers (IX).

Alternatively, aminoaryl ethers (IX) wherein R¹⁵ is aryl or heteroaryl may be prepared as depicted in Scheme 25. An acetamido-phenol can undergo copper-mediated

reactions with aryl or heteroaryl boronic acids to yield the corresponding aryl ethers. These ether intermediates can then be deprotected under typical conditions to provide the desired diaryl ethers of formula (IX) wherein R^{15} is aryl or heteroaryl. Thus, for example, reaction with a substituted phenyl-boronic acid can afford the corresponding diphenyl ether, which can be deprotected and then incorporated into amides of formulae (I-IV).

Scheme 25. Alternate synthesis of aminoaryl ethers (IX).

10

Compounds of formula (I) wherein R^4 is acyl or sulfonyl may be prepared as depicted in Scheme 26. Here, amides of formula (I) in which R^4 is benzyl can be converted to amides (I) in which R^4 is hydrogen under typical conditions such as via palladium-catalyzed hydrogenation. The resulting pyrroles can then undergo reactions with suitable electrophiles such as, for example, acid chlorides to yield the corresponding amides (Id), equivalent to formula (I) wherein R^4 is acyl. Likewise, the pyrrole intermediate can react with sulfonyl chlorides to afford various amides (i.e), equivalent to formula (I) wherein R^4 is sulfonyl.

EXAMPLE 1

5 PREPARATION OF 1-(4-FLUORO-2-TRIFLUOROMETHYL-PHENYL)-2,5-DIMETHYL-1H-PYRROLE-3-CARBALDEHYDE

10 A. A mixture of 4-fluoro-2-(trifluoromethyl)aniline (4.4 g, 24.6 mmol), 2,5-hexanedione (2.8 g, 24.5 mmol) and acetic acid (0.28 mL) was heated to 100 °C. After 3h the reaction mixture was cooled and partitioned between EtOAc and water. The organic layer was separated, dried (MgSO₄), and concentrated in vacuo. The residue was purified by flash chromatography (SiO₂), eluting with EtOAc/Hex (0:100 to 10:90) to afford 1-[4-fluoro-2-(trifluoromethyl)phenyl]-2,5-dimethyl-1H-pyrrole as a yellow oil
15 (3.19 g, 50%); ¹H NMR (CDCl₃): δ 7.52(dd, *J* = 8, 3 Hz, 1H), 7.35(dt, *J* = 3, 8 Hz, 1H), 7.25(dd, *J* = 5, 8 Hz, 1H), 5.90(s, 2H), 1.91(s, 6H); MS (ESI) *m/z* 258 [M+H]⁺.

To anhyd DMF (10 mL) cooled under nitrogen to 0 °C was added phosphorous oxychloride (1.2 mL, 13.1 mmol). The resulting mixture was stirred at 0 °C for 30 min
20 and then a solution of 1-[4-fluoro-2-(trifluoromethyl)phenyl]-2,5-dimethyl-1H-pyrrole (3.19 g, 12.4 mmol) in anhyd DMF (15 mL) was added portionwise. The reaction mixture was maintained at 0-3 °C for 10 min and then the reaction flask was heated on an oil bath at 95-100 °C. After heating 1.5 h, the reaction mixture was cooled and poured onto 200 mL of ice cold 1 M NaOH. The resulting suspension was extracted
25 twice with DCM. The combined extracts were dried (Na₂SO₄) and concentrated in vacuo. The residue was purified by flash chromatography (SiO₂), eluting with EtOAc/Hex (10:90 to 30:70) to afford the title compound as a light yellow solid (1.3 g, 37%); ¹H-NMR (CDCl₃): δ 9.90(s, 1H), 7.58(dd, *J* = 8, 3 Hz, 1H), 7.43(m, 1H), 7.29(dd, *J* = 5, 8 Hz, 1H), 6.39(s, 1H), 2.20(s, 3H), 1.91(s, 3H); MS (ESI) *m/z* 286 [M+H]⁺.

PREPARATION OF 1-[4-FLUORO-2-(TRIFLUOROMETHYL)PHENYL]-2,5-DIMETHYL-1H-PYRROLE-3-CARBONYL CHLORIDE

- 5 B. To a solution of 1-[4-fluoro-2-(trifluoromethyl)phenyl]-2,5-dimethyl-1H-pyrrole-3-carbaldehyde (1.5 g, 5.3 mmol) in acetone (150 mL) was added a 0.3 M solution of KMnO₄ (150 mL). The reaction mixture was stirred 3h at room temperature and then was charged with 10% H₂O₂ (5 mL). After 15 minutes the reaction mixture was filtered and the filtrate was concentrated in vacuo to remove acetone. The remaining aqueous suspension was acidified with acetic acid. The precipitates were recovered by filtration
10 and dried under high vacuum to afford 1-(4-fluoro-2-(trifluoromethyl)phenyl)-2,5-dimethyl-1H-pyrrole-3-carboxylic acid (0.99 g, 62%) as a faintly yellow powder; ¹H NMR (CDCl₃): δ 7.56(dd, *J* = 8, 3 Hz, 1H), 7.41(m, 1H), 7.27(dd, *J* = 5, 8 Hz, 1H), 6.42(s, 1H), 2.21(s, 3H), 1.90(s, 3H); MS (ESI) *m/z* 302 [M+H]⁺.
- 15 To a suspension of 1-(4-fluoro-2-(trifluoromethyl)phenyl)-2,5-dimethyl-1H-pyrrole-3-carboxylic acid (0.65 g, 2.16 mmol) in anhyd toluene (5.0 mL) cooled to 0-3 °C were added thionyl chloride (0.25 mL) and DMF (20 μL). The reaction mixture was allowed to warm to room temperature where it remained for 3 h and then was concentrated in vacuo. The residue was evaporated twice from 5 mL of toluene to remove thionyl
20 chloride and then was triturated in 3 mL of hexanes. The solids were removed by filtration and the filtrate was concentrated under reduced pressure and dried under high vacuum to afford the title compound (0.44 g, 64%) as a pale brown solid; ¹H NMR (CDCl₃): δ 7.59(dd, *J* = 8, 3 Hz, 1H), 7.44(m, 1H), 7.27(dd, *J* = 5, 8 Hz, 1H), 6.51(s, 1H), 2.17(s, 3H), 1.89(s, 3H); MS (ESI) *m/z* 320 [M+H]⁺.

EXAMPLE 2

25 PREPARATION OF 2,5-DIMETHYL-1-[2-(TRIFLUOROMETHYL)PHENYL]-1H-PYRROLE-3-CARBOXYLIC ACID PHENYLAMIDE AND VARIATIONS

A. A 0.125 M stock solution of 1-[2-(trifluoromethyl)phenyl]-2,5-dimethyl-1H-pyrrole-3-carboxylic acid chloride was prepared in THF. Anilines and other heterocyclic amines
30 were individually weighed and were dissolved to 0.125 M using a Tecan Genesis workstation and a 1.0 M diisopropylethylamine in THF solution. The Tecan was used to dispense 200 μ L of 0.125 M 1-[2-(trifluoromethyl)phenyl]-2,5-dimethyl-1H-pyrrole-3-carboxylic acid chloride to each reaction vessel and then was used to dispense 200 μ L of amine stock solutions to individual reaction vessels. The reaction vessels were
35 sealed and were allowed to react, at room temperature with agitation, for 18 h. The

reaction vessels were then unsealed and THF (0.90 mL) was added. The THF was removed by filtration and the reaction vessels were washed with 2 X 500 μ L of THF. Sample solutions were dried *in vacuo*.

- 5 B. Samples were dissolved in 500 μ L of DMSO and 500 μ L of methanol. Purity was determined by LC-MS using a combination of UV₂₅₄, UV₂₂₀, and ELSD detection [purity = (UV₂₅₄+UV₂₂₀/2)]. The HPLC conditions were: 4.6 mm x 50 mm C18 column, 10-90% acetonitrile gradient over 5 minutes (mobile phases were H₂O with 0.05 % TFA and acetonitrile with 0.035 % TFA), with a flow rate of 3.5 ml/min. Samples below 80%
10 purity were purified using a mass-directed LC-MS purification. Purified samples were concentrated *in vacuo*, were dissolved in DMSO and were reformatted into 96 well microtiter plates. Samples were tested for purity using LC-MS and quantity was estimated by correlating ELSD response to a standard concentration-ELSD response curve. Samples then were concentrated to dryness and were dissolved in DMSO to a
15 final concentration of 10 μ M, based on ELSD quantification.

C. The following compounds were prepared in a manner similar to that described in Examples 2A-2B using the appropriate amines:

A solution of tin (II) chloride dihydrate (1.05 g, 4.7 mmol) in conc hydrochloric acid (4.2 mL) was added to 4-fluoro-4'-nitrobenzophenone (0.37 g, 1.5 mmol) in a mixture of DME (4 mL) and EtOH (5 mL) at such a rate that the internal temperature remained under 35°C. After 5h the reaction mixture was quenched by addition to ice-water (40 mL). The mixture was diluted with DCM (25 mL), made basic (pH = 11) by addition of

PREPARATION OF 2,5-DIMETHYL-1-[2-(TRIFLUOROMETHYL)PHENYL]-1H-PYRROLE-3-CARBOXYLIC ACID [4-(METHANESULFONYL)PHENYL]-METHYL-AMIDE

To a solution of 4-methylsulfonyl-aniline (0.20 g, 1.2 mmol) in anhyd THF (2.0 mL) was added 1.43 M butyllithium in hexanes (0.82 mL, 1.2 mmol). The resulting suspension was sonicated to create a fine suspension and then iodomethane (80 μ L, 1.29 mmol, 1.1 eq) was added. The suspension was sonicated for 0.5 h and then was washed into a separatory funnel with EtOAc and water. The organic layer was separated, dried (anhyd MgSO_4), and concentrated in vacuo to afford a 4:1 mixture of (4-methylsulfonyl-phenyl)-methyl-amine and (4-methylsulfonyl-phenyl)-dimethyl-amine as a tan solid (180 mg). The crude mixture was used directly in the next step without purification.

15 PREPARATION OF 3,5-DIMETHYL-4-(2-TRIFLUOROMETHYL-PHENYL)-1H-PYRROLE-2-CARBOXYLIC ACID ETHYL ESTER

- 20 To a solution of ethyl 3,5-dimethyl-1H-pyrrole-2-carboxylate (3.42 g, 20 mmol) in carbon tetrachloride (40 mL) was added a solution of bromine in carbon tetrachloride (10 mL) dropwise at 20 °C. After the addition was complete, stirring was continued for 2h. The reaction mixture was diluted with DCM, washed with aqueous NaHCO₃ and water, and then dried over Na₂SO₄. Evaporation of solvent gave ethyl 4-bromo-3,5-
- 25 dimethyl-1H-pyrrole-2-carboxylate as a solid (4.8 g), which was used in the next step without purification. ¹H-NMR (CDCl₃): δ 9.36 (1H, s), 4.30(2H, q), 2.28 (3H, s), 2.26 (3H, s), 1.36 (3H, t).
- To a solution of ethyl 4-bromo-3,5-dimethyl-1H-pyrrole-2-carboxylate (2.4 g, 10 mmol) in DMF (25 mL) was added tetrakis(triphenylphosphine)palladium (2.3 g, 1 mmol).
- 30 After stirring 15min, the reaction mixture was charged with 2-(trifluoromethyl)-benzeneboronic acid (2.4 g, 12.5 mmol) and sodium carbonate (in 5 mL of water). The reaction mixture was heated to reflux overnight with stirring. After cooling, the reaction mixture was then diluted with water and extracted with DCM. The combined extracts

were washed with water and dried over Na_2SO_4 . Evaporation of solvent gave a crude material, which was purified by chromatography on silica gel column eluting with EtOAc-hexane (1:1) to give the title compound (1.5 g). MS (ES): 312 (MH^+)

5 PREPARATION OF 3,5-DIMETHYL-4-(2-TRIFLUOROMETHYL-PHENYL)-1H-PYRROLE-2-CARBOXYLIC ACID (4-METHANESULFONYL-PHENYL)-AMIDE

The precipitates were collected by filtration and washed with water, and then dried under high vacuum to afford 3,5-dimethyl-4-(2-trifluoromethyl-phenyl)-1H-pyrrole-
15 2-carboxylic acid (0.30 g). MS (ES): 284 (MH^+).

Into an oven-dried 1 dram vial was added 2,5-dimethyl-1-(2-trifluoromethyl-phenyl)-1H-pyrrole-3-carboxylic acid (3-hydroxy-phenyl)-amide (50 mg, 133 μmol), K_2CO_3 (22 mg, 160 μmol), 1-bromomethyl-4-fluoro-benzene (28 mg, 146 μmol) and 0.5 mL DMF. The

A. 1-[4-Bromo-2-(trifluoromethyl)phenyl]-2,5-dimethyl-1H-pyrrole-3-carboxylic acid [4-(methanesulfonyl)phenyl]-amide was prepared as described in Example 1G.

Into an oven-dried 1 dram vial was added 1-[4-Bromo-2-(trifluoromethyl)phenyl]-2,5-dimethyl-1H-pyrrole-3-carboxylic acid [4-(methanesulfonyl)phenyl]-amide (26 mg, 50 μ mol), 2,4-Bis(Trifluoromethyl)benzamide (13mg, μ mol) Copper (I) Iodide (50mg, 260 μ mol), K_2CO_3 (50 mg, 360 μ mol), N,N'-Dimethylenediamine (9 mg, 100 μ mol), and 0.4 mL of Toluene. The vial was sealed and stirred for 18h at 110 °C. The reaction was worked up by addition of a 1:1 solution of 2.0 M NaOH: 0.5M EDTA (1ml) and Ethyl Acetate (1ml). The vial was vortexed and the Ethyl Acetate was removed and dried in Vacuo. The crude material was purified by reverse-phase chromatography (C18 column), eluting with 0.05%TFA in MeCN/H₂O (30:70 to 90:10) to yield the title compound (6.9 mg, 10%) as a white solid. ¹H-NMR (DMSO-*d*₆): δ 11.24 (1H, s), 9.78 (1H, s), 8.28 (1H, d, *J* = 2 Hz), 8.22 (1H, d, *J* = 8 Hz), 8.19 (1H, s), 8.02 (4H, m), 7.76 (2H, d, *J* = 9 Hz), 7.44 (2H, d, *J* = 9 Hz), 6.59 (1H, s), 3.09 (3H, s), 2.10 (3H, s), 1.84 (3H, s); MS (ESI): 692 (MH⁺).

EXAMPLE 27 GAL4-MR CELL BASED ASSAY

Compound activity was determined in a cell-based assay using a GAL4-MR chimera to identify compounds with the ability to modulate MR activity.

The pCMX-GAL4-MR expression plasmid was constructed by cloning nucleotides encoding amino acids 671 to 984 of human MR (see GenBank sequence AAA59571) into the vector pCMX-GAL4 (Perlmann et al., 1993, Genes & Development 7:1411-1422) comprising nucleotides encoding for amino acids 1-147 of the GAL4 DNA binding domain.

The TK-MH100x4-Luc (GAL4_{UAS}-TK-Luciferase) reporter construct was constructed by insertion of four copies of the Gal4 UAS (Kang et al. 1993, J. Biol. Chem. 268:9629-9635) into the Hind III site of TK-Luc. The parental plasmid, TK-Luc, was prepared by insertion of the Herpes simplex virus thymidine kinase gene promoter

(-105 to +51) obtained from the plasmid pBLCAT2 by digestion with HindIII and XhoI (described in Luckow et al., 1987, Nuc. Acid. Res. 15:5490) into the plasmid MMTV-LUC described by Hollenberg and Evans, 1988, Cell 55:899-906) after removal of MMTV-LTR promoter sequence from MMTV-LUC via digestion with HindIII and XhoI.

5 Correct cloning was confirmed by restriction digestion and / or sequencing.

Assays were performed using CV-1 (African Green Monkey Kidney Cells) (ATCC) cells grown in T175 flasks at a density of 3×10^6 cells/flask in DMEM with 5% FBS. Cells were transfected one day after plating at 70-80 percent confluency with a DNA mixture containing (per T175 flask) 9 μ g pCMX-GAL4-MR, 9 μ g TK-MH100x4-Luc, and 2 μ g pCMX β -Gal using the transfection reagent FuGENE6 (Roche Molecular Biochemicals, Indianapolis, IN) following recommended protocols and instructions provided by the manufacturer, and incubated with transfection reagents for 5 hours at 37°C.

For the antagonist format, compounds were diluted in media containing aldosterone (30 nM) and dispensed into the assay plates using a Multimek (Beckman, Fullerton, CA). Approximately 5 μ l of media containing compound and aldosterone was dispensed into each well of the 384-well plate to achieve a final concentration of approximately 10 μ M for compounds and 3 nM for aldosterone. Transfected cells were trypsinized, resuspended in media, and 45 μ L was added to assay plates at a density of approximately 5,000 cells/well using a MultiDrop dispenser (MTX Lab Systems, Inc., VA). The assay plates containing both compounds and screening cells were incubated for approximately 20 hours at 37°C and 5% CO₂ in a tissue culture incubator.

After incubation of the transfected cells with compounds, Lysis buffer (1% Triton X-100, 10% Glycerol, 5 mM DTT, 1 mM EGTA, 25 mM Tricine, pH 7.8) and Luciferin assay buffer (0.73 mM ATP, 22.3 mM Tricine, 0.11 mM EDTA, 33.3 mM DTT, 0.2M MgSO₄, 11 mM Luciferin, 6.1 mM Coenzyme A, 0.01 mM HEPES, pH 7.8) were prepared. Media was removed from the plates and lysis buffer and luciferin assay buffer mixed in a 1:1 ratio and then 30 μ l of the mixture was added to each well using a Multidrop dispenser. Plates were read on the Northstar (Applied Biosystems, Foster City, CA) and data was analyzed using ActivityBase (ID Business Solutions, Ltd., Guildford, Surrey, UK). If required, luciferase values may be normalized for transfection efficiency by measuring β -galactosidase activity based on expression from the pCMX- β Gal expression plasmid as described previously (Willy et al., 1995, Gene & Development, 9:1033-1045).

In certain cases, compounds were also evaluated for activity in selectivity assays with other steroid hormone receptor members, including AR, ER, GR and PR, as well as GAL4 alone. Steroid receptors used for selectivity assays were essentially generated as described above for pCMX-GAL4-MR, and comprised the LBD and a portion of the hinge region of the nuclear receptor of interest cloned in frame into the vector pCMX-GAL4 (Perlmann et al., 1993, Genes & Development 7:1411-1422) as described above.

Assays run in antagonist mode included agonists as follows: AR; 25 nM dihydrotestosterone (DHT), ER; 4.5 nM estradiol, GR; 20 nM dexamethasone, and PR; 2 nM medroxyprogesterone (MPA), respectively. Assays run in agonist mode contained no supplemental compounds.

EXAMPLE 28 SCINTILLATION PROXIMITY ASSAY:

Preparation of protein lysates:

5 A baculovirus expression plasmid for human MR LBD was made by cloning a DNA fragment encoding amino acids 671-984 of human MR into the pBlueBacHis2, baculovirus transfer vector (Invitrogen, CA) following standard procedures. Insertion of the cDNAs into the pBlueBacHis2 vector polylinker created an in frame fusion to the cDNA to an N-terminal poly-His tag present in pBlueBacHis2 to yield vector
10 pBlueBacHis2-MR-LBD. Viral plaques were formed by co-transformation of pBlueBacHis2-MR-LBD with linearized Bac-N-Blue (Invitrogen, CA) into sf9 insect cells following the instructions provided with the reagents. Recombination between the two vectors resulted in the creation of MR-LBD baculovirus plaque. The virus stock was prepared following the manufacturers recommended protocols and used at a titer of
15 10^9 pfu/ml. Expression was confirmed by SDS-PAGE analysis after purification using Ni-NTA Resin (Qiagen) and western blotting using an anti-his antibody (Invitrogen, CA) using standard procedures. Correct cloning was confirmed by PCR and sequencing using specific primers.

20 Cell lysates were prepared by infecting healthy, Sf9 insect cells at a density of approximately 1.8×10^6 /ml at 27°C, in a total volume of 500 mL per spinner flask. Sf9 cells were infected use virus at an M.O.I of approximately 5 and incubated for 48 hours at 27°C with constant stirring prior to harvesting.

25 After incubation, cells were harvested by centrifugation and pelleted. Cell pellets were resuspended in ice-cold freshly prepared extraction buffer at 1/50 volumes of original culture (20 mM Tris-HCl pH 7.3, 1 mM EDTA, 10% Glycerol, 20 mM Sodium Tungstate, containing one EDTA free protease inhibitor tablet (Roche Catalog No: 1836170) per 10 ml of MR lysate buffer).

30 Cells were lysed on ice using a Branson Sonifier 450 set at an output of 1.5, 80% constant, for five sets of 15 beats to achieve 80-90% cell lysis. The homogenate was centrifuged in a pre-chilled rotor (SW55 or SW28, or equivalent) at 40,000 rpm for 20 minutes at 4°C. Aliquots of the supernatant were frozen on dry ice and stored frozen at -80°C until quantification and quality control. Aliquots of the lysates were tested in the SPA assay to ensure lot to lot consistency, and adjusted for protein concentration and expression level prior to use in screening assays.

35

Preparation of Screening Reagents:

[³H]-aldosterone ([³H]-Aldo) solution: For each 96-well plate (or 100 wells), 4.5 μL of [³H]-Aldo (70Ci/mmol, 1mCi/mL) was added to 3.6 mL of SPA Buffer with EDTA to provide for a final concentration of 14.7 nM. The ([³H]-Aldo solution for each additional
 5 96-well plate is prepared identically immediately prior to use. The final concentration of [³H]-Aldo in the well was 4.4 nM.

MR-LBD lysate (prepared as above) was diluted with MR lysate buffer. 1.5 mL of diluted MR-LBD lysate was prepared per 96-well plate, (or 100 wells). The MR lysate solution for each additional 96-well plate is prepared identically immediately prior to
 10 use. SPA bead solution: For a 96-well plate (or 100 wells), 600 μL of Ysi His-tag SPA beads (vortex well before taking) and 5.6 mL SPA buffer w/o EDTA were mixed together. The SPA bead solution for each additional 96-well plate is prepared identically immediately prior to use.

Procedure:

Appropriate dilutions of each compound were prepared and 10 μL was pipetted into the appropriate well(s) of a non-binding surface multiwell plate.

30 μL of [³H]-Aldo was added to each well of the multiwell plate.

10 μl of diluted MR-LBD lysate was added to each well of the multiwell plate.

20 50 μL of SPA bead solution was added to each well of the multiwell plate.

The plates were covered with clear sealer and placed in the Wallac Microbeta at ambient temperature for 30 minutes to one hour. After incubation plates were analyzed using a scintillation plate reader (Wallac Microbeta) using the program Robin96well3H. The settings for Robin96well3H were: Counting Mode: DPM / Sample
 25 Type: SPA / ParaLux Mode: low background / Count time: 2 minutes.

The determined Ki represents the average of at least two independent dose response experiments. The binding affinity for each compound may be determined by non-linear regression analysis using the one site competition formula to determine the IC₅₀ where:

30

$$Y = \text{Bottom} + \frac{(\text{Top} - \text{Bottom})}{(1 + 10^{X - \log \text{IC}_{50}})}$$

The Ki is then calculated using the Cheng and Prusoff equation where:

35 $K_i = \text{IC}_{50} / (1 + [\text{concentration of ligand}] / K_d \text{ of Ligand})$

For this assay, typically the concentration of ligand = 4.4 nM and the K_d of Aldo for the receptor is 5 nM as determined by saturation binding. The compounds of the invention demonstrated the ability to bind to hMR-LBD when tested in this assay.

EXAMPLE 29 AR- RECEPTOR HYDROXYLAPATITE BINDING ASSAY

Compound binding to AR was assessed by measuring the displacement of tritiated R1881 (an AR selective ligand) using a hydroxylapatite (HAP) binding assay to separate bound and free ligand using partially purified AR obtained from a cell lysate.

10 Partially purified AR was obtained from the MDA-kb2 cell line (ATCC) that endogenously expresses the full length AR. MDA-kb2 cells were grown in DMEM with 5% FBS in T175 flasks. When the cells reached about 80% confluency they were harvested and centrifuged at 1000 rpm for 5 min. The cell pellet was resuspended in AR buffer (10 mM TRIS, 10% glycerol, 1.5 mM EDTA, 1.0 mM sodium molybdate, 1
15 mM PMSF, 1.0 mM dithiothreitol, pH 7.4 at 4°C) and sonicated using a sonic probe (Sonifier 450, Branson) at a setting of 1.5, (80% constant) for five sets of 15 beats to achieve 80-90% cell lysis. After sonication, cells were incubated on ice for 10 minutes and then centrifuged in a pre-chilled rotor (SW55 or SW28, or equivalent) at 40,000 rpm for 20 minutes at 4°C. The supernatant was collected and placed on ice.

20 For the binding assay, MDA cell lysate (prepared as above) was diluted 1:2 in AR buffer and 300 µl pipetted into a 1.2 ml microcentrifuge tube. 50µl of triamcinolone (a selective GR antagonist) (Sigma, St. Louis, MO) was included in all assay tubes at a final concentration of 60 µM. Compounds to be tested were prepared in DMSO at a starting concentration of 945 µM and 10µl were added to the lysate preparation.

25 [³H]R1881 (NEN, Boston, MA) and was first diluted in AR buffer to create a stock concentration of 94.5 nM. 5 µl of the stock [³H]R1881 was then added to the lysate mixture to initiate binding. Non-specific binding was determined using cold R1881 at a 100-fold molar excess over the concentration of labeled [³H]R1881. The tubes were gently vortexed and incubated overnight at 4°C.

30 Following overnight incubation (18 hrs), the lysates were washed to remove unbound ligand. This was achieved by adding 100 µl of the lysate prep to 500µl of a 50% hydroxylapatite slurry contained in a 12x75 mm polypropylene tube. The tubes were then vortex mixed three times for 20 sec, allowing the tubes to incubate for five minutes between vortex mixings. After the final mixing, the tubes were centrifuged at

1780 rpm at 4°C for 5 minutes. The supernatant was decanted and the slurry was resuspended in AR buffer. This wash step was repeated four times. Following the final wash with AR buffer, the pellet was resuspended in 1.5 ml ethanol. The tubes were then vortex mixed for 20 sec every 5 minutes at room temperature. This was repeated
5 four times.

After the final mix the tubes were centrifuged at 1780 rpm at 4°C for 20 minutes. The supernatant was decanted into a 20 ml glass scintillation vial and 15 ml of Ecolume scintillation fluid was added. Samples were counted on a Beckman LS3801 scintillation counter (Fullerton, CA).

FORMULATION AND EXPERIMENTAL DESIGN

A. SOLUTION FORMULATION

Test article was administered intravenously at 3 mg/kg formulated in carrier
15 dosage vehicle suitable for IV administration of the test article. Oral solution (or suspension) doses of 3, 10, 30, 100, 300 and 1000 mg/kg were administered using a suitable carrier dosage vehicle. The compound was also administered at 10 mg/kg as a solid in gelatin capsules. Experimental groups were comprised of five animals for each dose group. Blood was collected (100 µL) in heparinized tubes via a jugular
20 catheter at 0.02, 0.08, 0.25, 0.5, 1, 2, 4, 6, 8, 10, 12, 24, 32, 48 and 72 hours post-dosing for the IV groups. Samples were similarly collected at 0.08, 0.25, 0.5, 1, 2, 4, 6, 8, 10, 12, 24, 32, 48 and 72 hours post-dosing for the PO groups. The plasma obtained was stored at -80°C and a volume of 50 µL was used for analysis.

25 B. SOLID DOSAGE

Torpac size 9 porcine gelatin mini capsules were used to orally dose test article in solid form at 3 or 10 mg/kg. Capsules were filled with powdered compound based on body weight. Capsules were administered directly into the rat's stomach with the use of a stainless steel dosing device similar to an oral gavage needle. Pilot studies with
30 empty capsules revealed that capsules dissolve in less than 7 minutes in the stomach.

BIOANALYTICAL ANALYSIS

The concentration of test article in plasma and tissue samples was determined by HPLC/MS/MS analysis using sample preparation and analytical conditions
35 appropriate for the test article quantification by this method. A non-compartmental

model was applied to calculate pharmacokinetic (PK) parameters for all routes of administration using WinNonlin 3.1 software (Pharsight Co., Mountain View, CA).

The compounds of the present invention exhibited greatly enhanced and improved pharmacokinetic properties.

EXAMPLE 31

KINETIC SOLUBILITY ASSAY

The kinetic solubility of test compounds in buffer was evaluated using a 96 well filtration plate format. A 500 μ M assay solution in PBS, pH7.4 (or other assay buffer, as needed) was generated from a DMSO stock solution (up to 10 mM). Samples were transferred to a 96 Millipore MultiScreen HTS 96-well Filter plate (Cat# MSSLBPC10) mixed by shaking for 1.5 hours and processed by filtration prior to quantitation by HPLC-UV. Amiodarone and testosterone were used as reference controls. In-house historical data shows that the solubility of amiodarone is between 3-5 μ M and testosterone is approximately 330 μ M. An Agilent Chemstation using a Waters 4 x 23mm threaded cartridge YMC/AQ S-5 120A C18 column was used for separation of analytes at a mobile phase flow rate of 2.2 mL/min. The mobile phase was 0.1% TFA in water (solvent A) and 0.1% TFA in acetonitrile (solvent B). The column was maintained at 37°C and detection of analytes was achieved by UV signal quantification at 220 nm and 254 nm following a 10 μ L injection volume.

15

The compounds demonstrated kinetic solubility in the range of for example, about 500 μ M or less, 400 μ M or less, 300 μ M or less, 200 μ M or less, 100 μ M or less. In an advantageous embodiment, the kinetic solubility is about 50 μ M or less, 20 μ M or less, 10 μ M or less, 5 μ M or less, 2.5 μ M or less, or 1 μ M or less.

EXAMPLE 32

The following table provides *in vitro* MR activity data of representative compounds described in the Examples. Average IC_{50} values for antagonist activity in the GAL4-MR assay are provided as follows: V: less than 0.5 μ M; W: 0.5 μ M-1 μ M; X: 1 μ M to 5 μ M. Average percent inhibition with respect to MR activity relative to a maximally effective concentration of Spironolactone (as determined in a dose response curve in the presence of 3 nM aldosterone), are provided as follows; A: 100-120% of control and B: 80-100% of control.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US05/26916

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☒ Claims Nos.: 1-12 and 14-124
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
Please See Continuation Sheet
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying additional fees, this Authority did not invite payment of any additional fees.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐

The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.

☐

The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.

☐

No protest accompanied the payment of additional search fees.

Box II Observations where certain claims were found unsearchable 2.:

because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically: In these claims, the numerous variables (e.g. R1, R2, R3, R4, R5, R6, R7, R8, R9, R10, R11, R12, R13, R14, R15 and t) their voluminous complex meanings, their seemingly endless permutations and combinations make it virtually impossible to determine the full scope and complex meaning of the claimed subject matter. As presented, the claimed subject matter cannot be regarded as being a clear and concise description for which protection is sought and as a result the listed claims do not comply with the requirements of PCT Article 6. Thus it is impossible to carry out a meaningful search of the same. A search will be made of the first invention in the claims, which is the first named compound of claim 12, 2,5-dimethyl-1-(2-trifluoromethyl-phenyl)-1H-pyrrole-3-carboxylic acid (4-methylsulfanyl-phenyl)-amide.
